Wastewater Aeration What it Does and How it Works

Problems with oxidized flavor may be caused primarily by low oxidative stability of the milk as produced, but are aggravated by abuse at any stage of processing and distribution. This copper is then picked up by the first milk that passes through the equipment after cleaning. Fortunately, blood provides a two-way street for transportation of feed flavors.

COLLECTION AND RECEPTION OF MILK

Hence, milk should be produced under conditions that give good flavor initially, and also be handled to protect its flavor at every step from the cow to the consumer. Various methods of deaeration are therefore used to avoid jeopardizing production and the quality of the products.

If necessary the system will then send the first pig back through the pipe to remove residual water or cleaning agents from the CIP, before again returning it to its housing.

Wastewater Aeration What it Does and How it Works

Examples are a medicinal flavor from salves used on the teats or udder, or chlorophenol flavor from plastic or rubber parts of the milking equipment. If flavors of bacterial origin develop in raw milk, this indicates that sanitary practices have been inadequate, or that the milk has been held at too high a temperature, or too long. The defect is encountered most frequently with dry feeds.

It also frequently results in longer storage times.
