Insect Neurobiology and Neuroecology (INN Lab)

Projection neurons supply protocerebral centres on the same side of the brain as the lobe from which they originate. An exceptionally preserved arthropod cardiovascular system from the early Cambrian.

Ant Brain vs Human Brain: What Humans Can Learn from Ants

The dopamine signals released by these cells are received in the mushroom body, a prominent in insect brains. This organization differs from that in pterygote insects, where, depending on species, the olfactory lobe provide as many as five ascending tracts to the protocerebrum;. Anatomy of the nervous system; 3.

Neurobiology

Kirby Neurobiology Center at Boston Children's Hospital, helping unravel the neurobiology behind such abnormalities in human motivation is the ultimate quest.

Experiments for Everyone

In particular, we are investigating the tympanal hearing organ of parasitoid tachinid flies, which parasitize crickets and locate them by homing in on the cricket's mating calls.

Brain organization and the origin of insects: an assessment

An attempt to resolve the phylogenetic relationships amongst the major arthropod groups has traditionally used morphological characters. The messenger substance dopamine is not only significant for and other insects.

Nicholas Strausfeld, Ph.D.

Mystery mutants: Using mutations at *Drosophila* neuromuscular junctions to teach principles of neuronal communication. In particular, we study the mate calls, rivalry calls, and courtship calls that are produced by crickets and katydids.
